

BOARD BRIEFING

Responsible AI

Looplo

Vision, mission and seven goals

How you can increase your use of AI without the control work growing with it.

Four conditions pulling in different directions

1

Spending is rising

The gain cannot be accounted for.
You pay for usage whose value cannot be quantified.

2

Competitors are moving

They do not carry your history.
Waiting is also a choice with a price.

3

Accountability is personal

Regulation places it on a person. It cannot be delegated away.

4

Every unit has its own solution

There is no single picture of what runs where.

They look like four separate problems. They share one cause.

There is no place where your own concepts live, are versioned and have an owner.

The models know the language. Not your reality.

What a language model knows

How a case is usually written about. Which words travel together. What a well-formed answer looks like.

A well-formed answer can be wrong.

What it does not know

What a case is at your organisation. What it may lead to. When it is closed. Who may decide it.

It is written down nowhere, including at your organisation.

So every decision can only be checked by a human being

And the control work grows faster than the usage, because the systems call each other.

You should be able to increase your use of AI without the control work growing with it.

This is not an ambition about more technology. It is an ambition about a way of operating where the routine passes on its own with a trail that holds, and where your people see only what falls outside.

Usage

up

Control hours

down

Traceability

unchanged, high

You move the control from inspection to construction.

Inspection

Treats the symptom one decision at a time. A human must read every answer. The burden rises with usage.

Ongoing cost

Construction

Removes the need for most of it. If a decision can only be expressed in concepts you defined yourself, most of it is right the moment it is made.

One-off work with declining upkeep

The difference is not how thoroughly you check. It is how many decisions need checking at all.

GOALS

Seven states you are either in or not in

1

You know what you have under control

MADE TANGIBLE BY

A register of the couplings between your domains, with a named owner per coupling and a state that can be read without interpretation.

2

Every decision can be justified

MADE TANGIBLE BY

An event chain that cannot be altered retroactively, where the answer can be produced in hours rather than weeks, a year later too.

3

Your concepts mean the same across the organisation

MADE TANGIBLE BY

A concept set with version numbers and ownership, where disagreement stands as open items rather than as repeated meetings.

4

Control work falls as usage rises

MADE TANGIBLE BY

Hours spent on inspection measured before and after, set against the number of decisions. The two curves must diverge.

Stated as states, not as projects. A board can determine whether a state has been reached.

GOALS

Goals 5 to 7

5

You can change supplier without losing anything

MADE TANGIBLE BY

A completed exercise where everything is exported in open formats, the system is deleted, and everything is loaded back in, without loss of data or history.

6

Accountability is placed, not distributed

MADE TANGIBLE BY

An overview the board can read, where every critical area of responsibility has one person and a date of last confirmation.

7

You own the layer yourselves

MADE TANGIBLE BY

That you can maintain and extend the concept set without outside help, and that this has been tested at least once.

Goals 5 and 7 are the two that decide whether you own the result or merely borrow it.

Planen

Fem trin. Trin 1 til 4 gør ondt mindre. Trin 5 fjerner årsagen.

TRIN	SMERTEN I DAG	HVAD I FÅR	HVAD DET KRÆVER AF JER
Trin 1 Håndholdt oprydning	Ingen ved samlet hvor koblingerne mellem domænerne går, eller hvem der ejer dem. Diskussionerne gentages fordi der ikke findes et fælles billede.	Et register over koblingerne med navngiven ejer og en tilstand der kan aflæses uden fortolkning. Konstrueret i hånden, ikke genereret.	Et rådgivningshonorar og adgang til folk. Ingen software i driften. Seks til ni måneder.
Trin 2 Digitaliseret vedligehold	Koblingerne ændrer sig hver uge - nyt system, ny leverandør, ny person i en rolle. Kortlægningen forældes, og ingen kan følge med i hånden.	Et værktøj i jeres eget miljø hvor koblingerne holdes ved lige løbende. Ændringer registreres når de sker, og historikken kan ikke rettes bagud.	Et miljø, en nøgle og læseadgang til to systemer. Og at ejerne faktisk bruger værktøjet. Ingen data forlader huset.
Trin 3 Semantisk lag	Tre afdelinger mener tre ting med det samme ord. Uenigheden har intet sted at blive afgjort og bliver til møder.	Jeres begreber skrevet ned, versioneret og med ejerskab. Uenighed står som åbne punkter i stedet for som gentagne møder.	Tid fra fagfolk - og en beslutning om hvem der afgør en uenighed når den opstår.
Trin 4 Delvis automatiseret verifikation	Hvert svar fra et system skal læses af et menneske. Byrden vokser hurtigere end anvendelsen, fordi systemerne kalder hinanden.	Rutinen passerer automatisk fordi svaret kan holdes op mod laget. Jeres folk ser kun det der falder udenfor. DELVIS: en del kræver stadig et menneske, og SYMPTOMBEHANDLING - fejlen opstår, den fanges bare.	At en arbejdsgang lægges om, og at nogen med mandat afgør hvor grænsen for rutine går.
Trin 5 Semantisk forretningsmodel	Kontrollen fanger fejl efter de er opstået. Modellerne handler stadig uden for jeres virkelighed - vi opdager det bare hurtigere.	Jeres forretning findes som en model systemerne handler inde i. En forkert handling kan ikke udtrykkes, fordi den ikke findes i modellen. MEKANISMEN, ikke plasteret.	At arkitekturen implementeres, ikke kun beskrives. Flerårigt - og I ejer modellen, ikke låner den.

HVERT TRIN GØR DET NÆSTE MULIGT

The first step requires no software in operations, no new supplier category and nothing that needs security approval.

Why the order cannot be reversed

Maintenance presupposes cleanup

The couplings must be mapped and owned before a tool can keep them up to date.

The layer presupposes maintenance

A living picture shows where your concepts actually diverge, not where someone believes they do.

Verification presupposes the layer

There must be a concept set to decide against, otherwise the control has merely moved.

The architecture presupposes verification

The rules from the control are the building blocks. You do not implement something that has not proved itself in operation.

Jump straight to verification and you buy relief without a foundation, and the burden returns as soon as usage rises again.

THE DIFFERENCE BETWEEN STEP 4 AND STEP 5

Treating symptoms is not a mistake. It is simply not the end point.

STEP 4 • PARTLY AUTOMATED VERIFICATION

The agent acts. We check afterwards.

- The error occurs, it is merely caught
- The control must be maintained forever
- Only form can be checked automatically
- Some of it still needs a human, the burden falls but does not disappear

STEP 5 • SEMANTIC BUSINESS MODEL

The business exists as a model.

- A wrong action cannot be expressed
- The model carries the rules, not the control
- Content can be decided too, not only form
- The need is removed rather than managed

Step 4 is not wasted work. The rules you write into the control are the first building blocks of the model.

Step 5 is therefore not a fresh start but a consolidation of something that has already proved itself in operation.

What a semantic business model consists of

Not a glossary and not a document. An implemented architecture the systems operate inside.

1

The object model

Classes, properties and relations

What a case, an order or an asset is. Which properties it has, and how it connects to everything else.

2

Lifecycle and rules

States and permitted transitions

Which states something can be in, which transitions are lawful, and who may trigger them. The legal basis lives here.

3

Causal knowledge base

Relations with probability

When these conditions hold, this typically follows. Built from your own instances over time, not from general knowledge.

4

The agent layer

The systems that act

The agents read and write in the model rather than in free text. If the symbol does not exist, the action cannot be carried out.

The first three parts are yours and never become anything else. The fourth layer can be replaced without the other three changing.

Four questions the board should ask

- 1 Does the diagnosis hold? Are the four conditions really one problem, or are they separate?
- 2 Who is liable today for a decision made by a system, and does that person know it?
- 3 What does the inspection cost in a year, if usage doubles and the form is unchanged?
- 4 What happens to your measurements the day you change supplier?

The first question is the most important. If the diagnosis does not hold, neither does the rest.

VISION

You should be able to increase your use of AI without the control work growing with it.

MISSION

You move the control from inspection to construction.

SEVEN GOALS

- You know what you have under control, the dependencies are mapped and owned
- Every decision can be justified, mandate, model, basis and action can be produced
- The concepts mean the same across the organisation, versioned, with ownership
- Control work falls as usage rises, measured before and after
- You can change supplier without losing anything, tested, not promised
- Accountability is placed, not distributed, names rather than departments
- You own the layer yourselves, the foundation does not live with an adviser
